1. Recap

Earlier in the stage of this project. Exploratory Data Analysis is conducted on the dataset and came to understanding of attributes relations with target variable which is Insurance Cost.
Picked Top 15 Features from the data by some Clustering techniques.

The Top 15 Features which has very strong importance when compared to Target Variable are these:

1. years_of_insurance_with_us
2. regular_checkup_lasy_year
3. visited_doctor_last_1_year
4. cholesterol_level
5. age
6. avg_glucose_level
7. bmi
8. smoking_status
9. weight
10. Alcohol
11. exercise
12. weight_change_in_last_one_year
13. fat_percentage
14. Gender_Male
15. covered_by_any_other_company_Y

These features are considered for the Next phase of the project which is Model Building.

2. Data Preparation

Splitting the Data into Train and Test which are in 70 and 30 proportions respectively.

```
Number of rows in train data = 17500
Number of rows in test data = 7500
```

3. Model Building

Total 8 Models are planned to build on this dataset.

1. 4 Parametric Models
    a. OLS Model
    b. LASSO Regression Model
    c. Ridge Regression Model
    d. Polynomial Regression Model
2. 4 Non-Parametric Models
    a. Random Forest Regression Model
    b. XG Boost Regression Model
    c. AdaBoost Regression Model
    d. Support Vector Machine (SVM) Regression Model

3.1 Parametric Models

3.1.1 OLS Model

```
                            OLS Regression Results
==============================================================================
Dep. Variable:         insurance_cost   R-squared:                       0.945
Model:                            OLS   Adj. R-squared:                  0.944
Method:                 Least Squares   F-statistic:                 1.985e+04

==============================================================================

Notes:
[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.
```

Figure 1: Model Summary

3.1.2 Model Performance on Training data

Training Performance

	RMSE	MAE	R-squared	Adj. R-squared	MAPE	Model
0	3383.976844	2726.866303	0.94454	0.944489	15.364108	OLS Model

Figure 2: Model Summary

Model Evaluation checks

1. TEST FOR MULTICOLLINEARITY

    a. If VIF is between 1 and 5, then there is low multicollinearity.
    b. If VIF is between 5 and 10, we say there is moderate multicollinearity.
    c. If VIF is exceeding 10, it shows signs of high multicollinearity.

	feature	VIF
0	const	117.968023
1	years_of_insurance_with_us	1.074730
2	cholesterol_level	1.012511
3	age	1.000604
4	avg_glucose_level	1.001233
5	bmi	1.181960
6	weight	1.195902
7	weight_change_in_last_one_year	1.171035
8	fat_percentage	1.010097
9	regular_checkup_lasy_year	1.024778
10	visited_doctor_last_1_year	1.004790
11	smoking_status	1.094231
12	Alcohol	1.004201
13	exercise	1.001658
14	Gender_Male	1.200788
15	covered_by_any_other_company_Y	1.081473

Figure 3: VIF Summary

- There are no multiple columns with very high VIF values, indicating no presence of multicollinearity

- We will systematically drop numerical columns with VIF > 5
- We will ignore the VIF values for dummy variables and the constant (intercept)

2. **Linearity of variables**
3. **Independence of error terms**
4. **Normality of error terms**
5. **No Heteroscedasticity**

	Actual Values	Fitted Values	Residuals
4289	28382.0	29604.903540	-1222.903540
19621	23446.0	20769.153934	2676.846066
14965	46892.0	44276.790919	2615.209081
12321	40722.0	45462.870559	-4740.870559
6269	32084.0	35857.236859	-3773.236859

Figure 4: Predicted values

Figure 5: Residual Chart

- The scatter plot shows the distribution of residuals (errors) vs fitted values (predicted values).

- If there exist any pattern in this plot, we consider it as signs of non-linearity in the data and a pattern means that the model doesn't capture non-linear effects.
- **We see no pattern in the plot above. Hence, the assumptions of linearity and independence are satisfied.**

6. TEST FOR NORMALITY

Figure 6: Normality of Residuals

- The histogram of residuals does have a bell shape.
- Let us check the Q-Q plot.

Figure 7: Q-Q Plot

7. Shapiro Test

```
ShapiroResult(statistic=0.987649019540111, pvalue=5.266053488552379e-36)
```

- Since p-value < 0.05, the residuals are not normal as per the Shapiro-Wilk test.
- Strictly speaking, the residuals are not normal.
- However, as an approximation, we can accept this distribution as close to being normal.
- **So, the assumption is satisfied.**

8. F Statistic Test

```
[('F statistic', 1.0007029442440367), ('p-value', 0.4869032216102235)]
```

Figure 8: F-Statistic

Since p-value > 0.05, we can say that the residuals are homoscedastic. So, this assumption is satisfied.

3.1.3 Model Performance on Test data

```
Test Performance
```

	RMSE	MAE	R-squared	Adj. R-squared	MAPE	Model
0	3340.182673	2711.95957	0.94479	0.944672	15.115261	OLS Model

Figure 9: Model Summary

- The model can explain ~94% of the variation in the data

3.1.4 LASSO Regression Model

LASSO Coefficients and Intercepts

```
Lasso Coefficients: [   0.          -12.26374286   23.49492635    2.81254998   53.72218469
   24.29975337 1490.45354718  174.38205263  -26.46086157 -450.99606236
  -32.33464418   -6.57755496   15.78393108   -6.23876337   23.62149231

Figure 34: Model Summary

All models have given MAPE less than 15% on test data compared with Train data

This performance is in line with what we achieved with this model on the train and validation sets

So, picking top 2 models to check feature importances

3.3 Feature Importance of Tuned Random Forest Model

3.4 Feature Importance of Tuned XG Boost Model

3.5 Interpretation of the Most Optimum model

Tuned XG Boost:

- The Tuned XG Boost model stands out as the most accurate and business-aligned choice in lineup. With a MAPE of just 12.26%, it offers exceptionally tight forecasting performance.
- Its R-squared value of 0.9527 confirms that it captures over 95% of the variance in the target variable, signifying strong feature.
- The model also posted the lowest RMSE and MAE, smoother performance across diverse customer profiles.
- In terms of feature behaviour, XG Boost places overwhelming emphasis on “weight”. Other features like coverage by another insurance company and regular health checkups register minor but intuitive signals, highlighting behavioural and contextual flags.

Tuned Random Forest:

- The Tuned XG Boost model stands out as the slightly lesser accurate than Tuned XG Boost model. With a MAPE of just 13.76%, it offers exceptionally tight forecasting performance.
- Its R-squared value of 0.9457 confirms that it captures over 94% of the variance in the target variable, this model still delivers highly dependable performance — just a notch below XG Boost.
- The slightly higher RMSE and MAE suggest broader prediction intervals but remain well within acceptable thresholds.
- In terms of feature behaviour, Random Forest truly shines in its clarity of feature importances. Not only does it reaffirm **weight** as the primary driver ~80% importance, but it also surfaces **weight change in the last year** as a meaningful secondary signal ~10%. Other features like **checkups**, **age**, **tenure**, and **lifestyle indicators** contribute minimally
